

# Methane mitigation in ruminants: from rumen microbes to the animal

C. Martin, M. Doreau, D.P. Morgavi  
INRA Clermont-Ferrand/ Theix, FRANCE

# The production of greenhouse gases (GHG) from livestock is a major concern (FAO 2006)

**Enteric methane (CH<sub>4</sub>) is the most important contributor of GHG emissions in ruminant production**

## Enteric CH<sub>4</sub> production by ruminants

- 33% of the European Union's agricultural GHG emissions

- loss in productive energy for ruminant : mean 6-7%, 2-12% GEI  
**Johnson and Johnson 1995**

## Development of strategies to mitigate CH<sub>4</sub> emissions

- environmental benefit for the planet

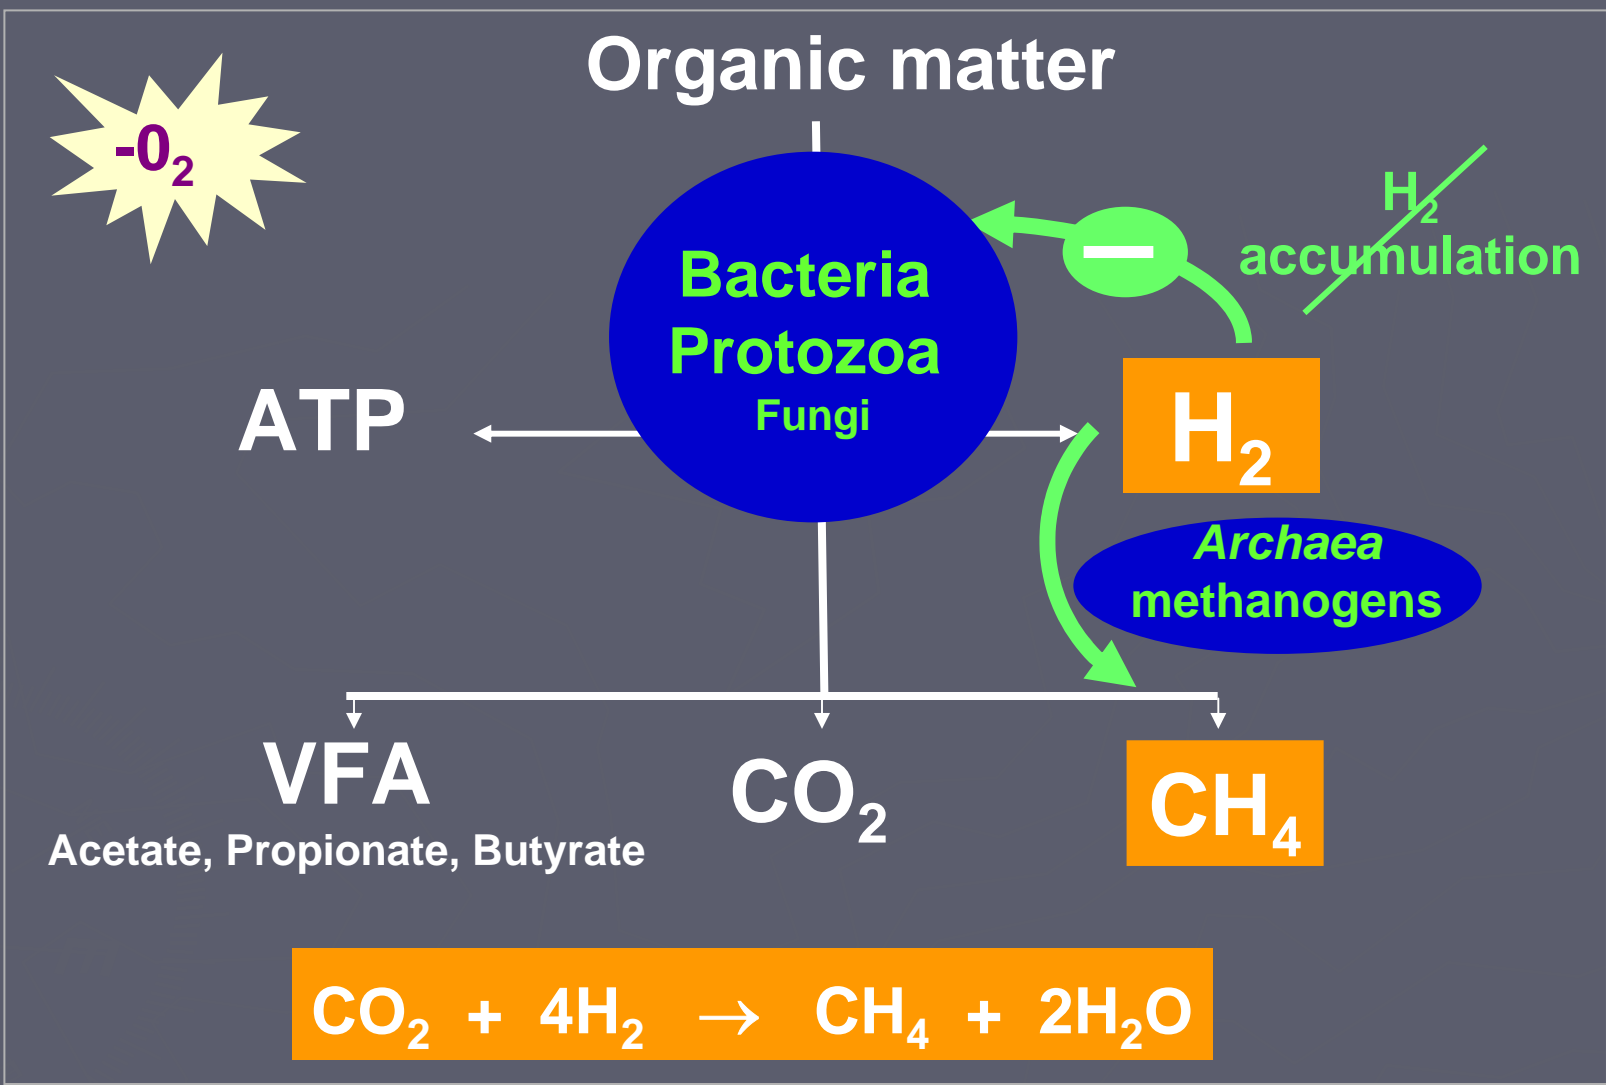

- nutritional benefit for the animal

# Where is CH<sub>4</sub> produced in the digestive tract ?

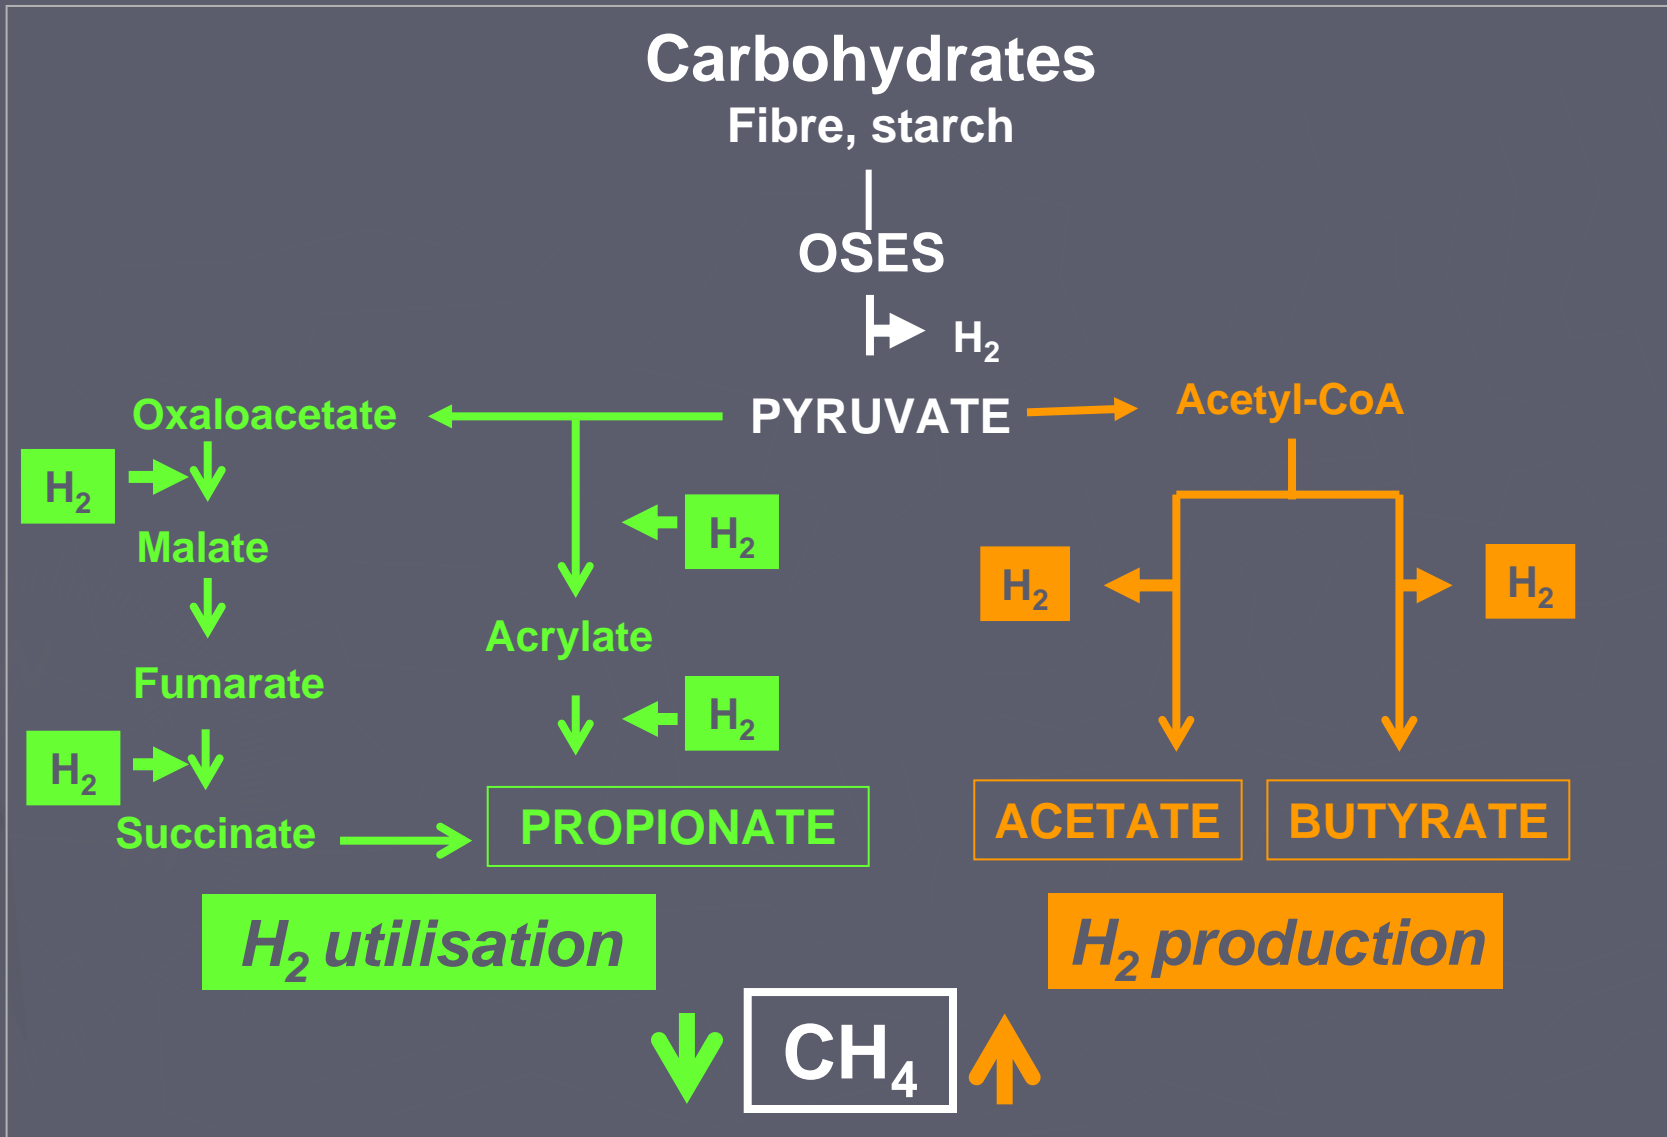

**CH<sub>4</sub> is mainly produced in the rumen  
and eliminated orally into the atmosphere**

# Why is CH<sub>4</sub> produced in the rumen?

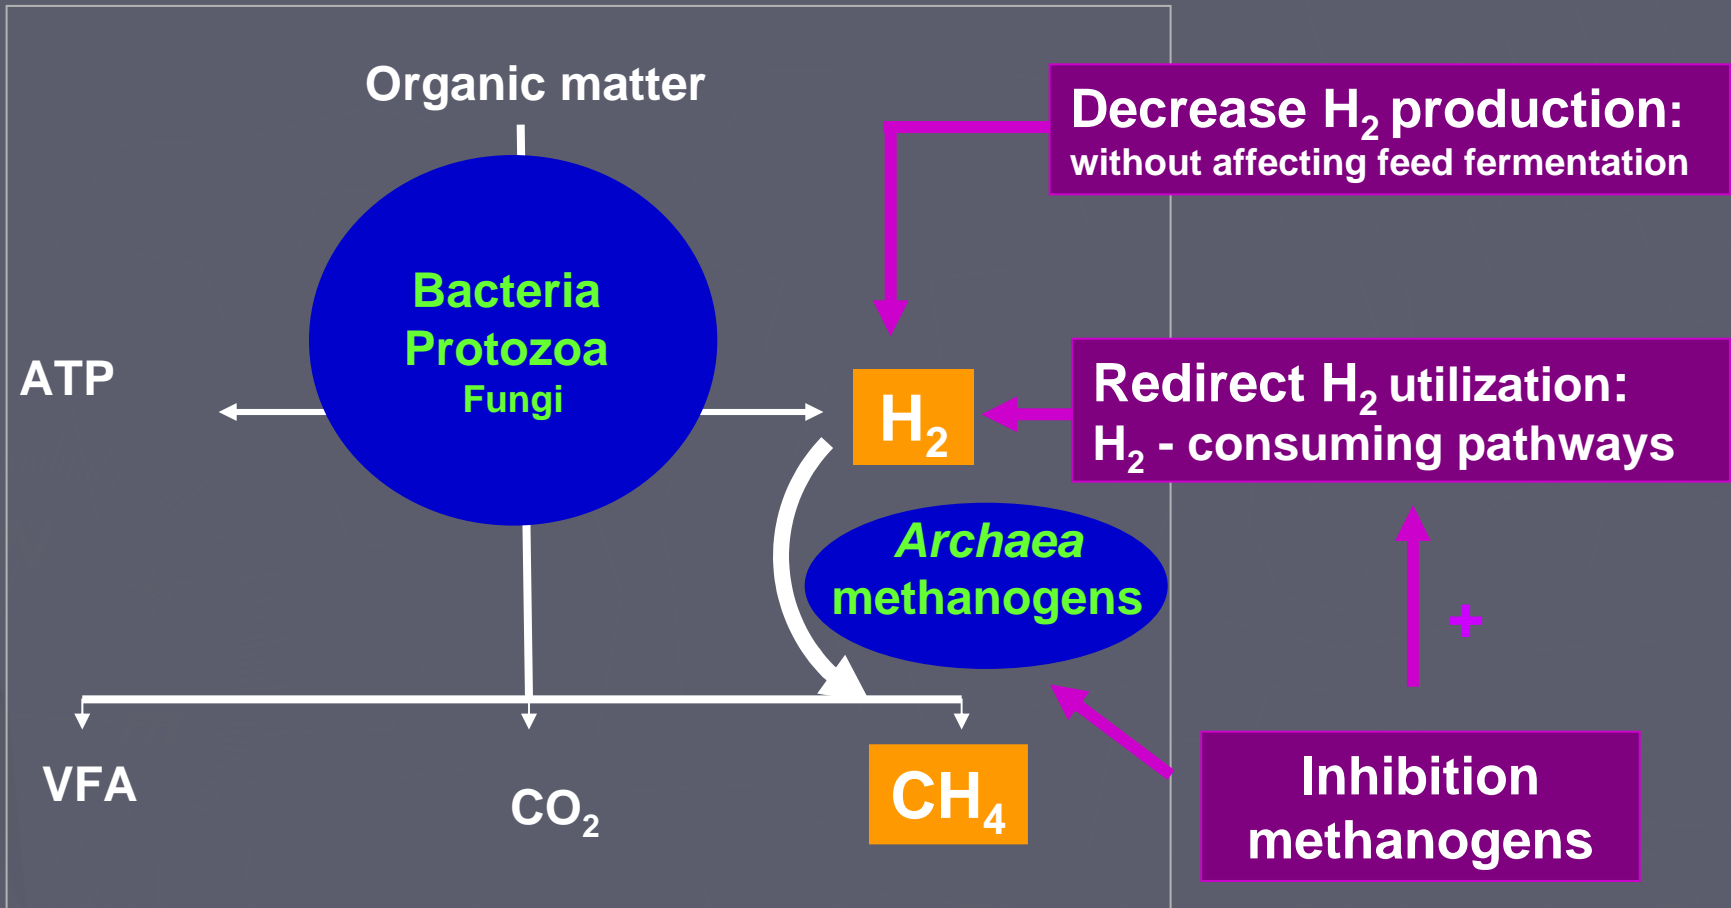

**CH<sub>4</sub> is the main pathway for removing H<sub>2</sub> generated during ATP production by anaerobic microbes**

# Microbial fermentation patterns are not equivalent in term of H<sub>2</sub> metabolism and methanogenesis

Two key points:

## H<sub>2</sub> metabolism and methanogens

- 1. Biotechnologies**
- 2. Additives**
- 3. Feeding**

# 1. Biotechnologies

**Promising but need more research**

# 1. Biotechnologies

## Defaunation

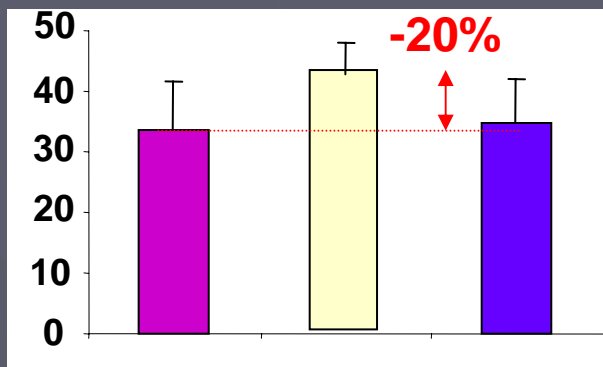

Chemical agents, plant extracts (saponins), FA

► Inhibition of protozoa (H<sub>2</sub>-producers, association with methanogens)

- ~ 25% reduction **Hegarty 1999**
- Transient effect **Ranilla et al 2004**

### Methane

-20% in long- and short-term defaunated sheep: permanent effect

### Propionate

Shift towards propionate

### Methanogens

Number similar  
Diversity similar

- decrease availability of H<sub>2</sub> rather than to a direct effect on methanogens
- commercial technique of defaunation need to be developed

Morgavi et al 2008  
Mosoni et al 2008

## 2. Additives

### Antibiotics

✓ Monensin, lasalocid, salinomycin, avoparcin...

- ▶ Inhibition of H<sub>2</sub>-producing bacteria (Gram+) and protozoa
- ▶ Shift of fermentation towards C3

- ▶ Permanent effect ?
- ▶ Forbidden as additives in the EU (01/2006)

### Chemical additives

✓ Sulfated AA (cysteine...)  
 ✓ 9,10 anthraquinone  
 ✓ Halogenated analogue of methane (chloroform...)

- ▶ H<sub>2</sub> metabolism
- ▶ Inhibition of methanogens

- ▶ Mainly studied in vitro
- ▶ Toxicity proven or probable ??
- ▶ Not marketable (!)

**Not an alternative**

## 2. Additives

### Plant extracts

- ✓ Essential oils (garlic extract, cinnamon...)
- ✓ Tannins
- ✓ Saponins (yucca, lucerne)

### Inhibition

- ▶ Methanogens
- ▶ Protozoa

- ▶ Good image as natural products
  - ▶ Mainly in vitro and highly variable
  - ▶ More in vivo trials are needed (optimal dose, transient effect, residues in animal products ...)
- Calsamiglia et al 2007

### Organic acids

- ✓ Malate, fumarate

Shift of H<sub>2</sub> towards C<sub>3</sub>

- ▶ Inconsistent effect : 0 to -75%
  - ▶ Efficient at 10% of intake : problems of cost and acidity – encapsulated fumarate
- Wallace et al 2006

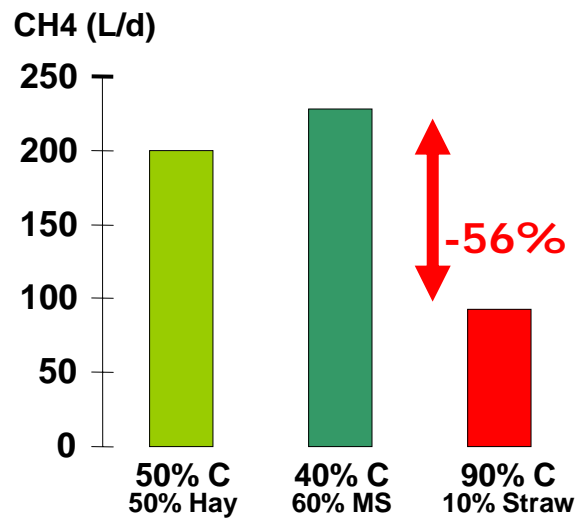

**To be confirmed**

### 3. Feeding: concentrate

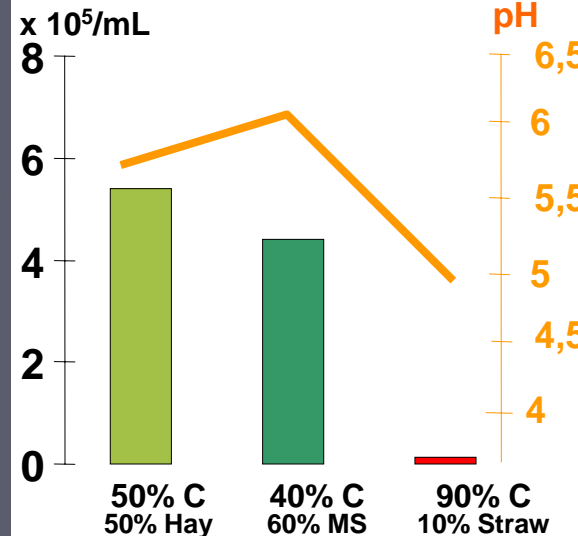

Martin et al 2007

#### Methane

Methane 2 times lower with the diet containing 90% C

#### Protozoa and ruminal pH

Decrease in protozoa and ruminal pH

#### Propionate

No change in C3

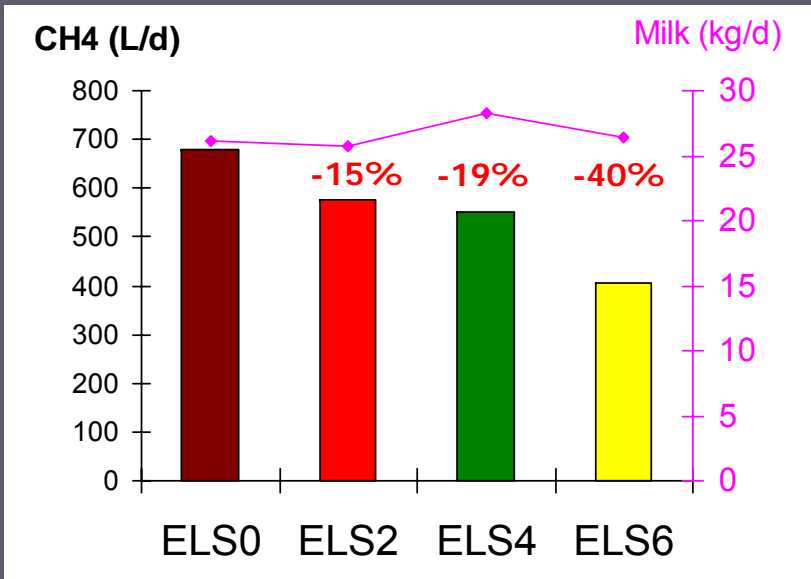

- decrease in H<sub>2</sub> production and methanogenesis

- increase digestive perturbation and health problems
- increase other GHG emissions at farm scale

### 3. Feeding: lipids

CH<sub>4</sub> and milk  
Martin et al 2007

Linear decrease of methanogenesis

Microbes numbers and VFA  
Mosoni et al 2008

|                 | H <sub>2</sub> -producers |                       | H <sub>2</sub> -utilizers | VFA |
|-----------------|---------------------------|-----------------------|---------------------------|-----|
|                 | Protozoa                  | Cellulolytic bacteria | Archaea methanogens       | C3  |
| 1h pre feeding  | →                         | →                     | →                         | →   |
| 3h post feeding | ↘                         | Not determined        | Not determined            | →   |

Before feeding : no modification

After feeding : protozoa decrease and ??

- decrease H<sub>2</sub> production and methanogenesis
- post-prandial changes in hydrolytic and methanogenic microorganisms

- dose > 6% : negative effect on DMI and digestion process
- nature : PUFA = MCFA Machmüller et al 2003
- long term effect ??

# Methane mitigation is possible

**Feeding: most developed**  
**Biotechnologies and additives: promising**

## RESEARCH

- Combination between strategies

## APPLICATION

- Safety for the animal and the consumer
- Long term sustainability
- Cost
- Total net emissions of GHG at animal and farm scale

**Thank you for  
your attention**
